Audit Report

PIKAMOON

August 2025

Table of Contents

Risk Classification

The criticality of findings in Cyberscope's smart contract audits is determined by evaluating multiple variables. The two primary variables are:

1. **Likelihood of Exploitation**: This considers how easily an attack can be executed, including the economic feasibility for an attacker.
2. **Impact of Exploitation**: This assesses the potential consequences of an attack, particularly in terms of the loss of funds or disruption to the contract's functionality.

Based on these variables, findings are categorized into the following severity levels:

1. **Critical**: Indicates a vulnerability that is both highly likely to be exploited and can result in significant fund loss or severe disruption. Immediate action is required to address these issues.
2. **Medium**: Refers to vulnerabilities that are either less likely to be exploited or would have a moderate impact if exploited. These issues should be addressed in due course to ensure overall contract security.
3. **Minor**: Involves vulnerabilities that are unlikely to be exploited and would have a minor impact. These findings should still be considered for resolution to maintain best practices in security.
4. **Informative**: Points out potential improvements or informational notes that do not pose an immediate risk. Addressing these can enhance the overall quality and robustness of the contract.

Severity	Likelihood / Impact of Exploitation
● Critical	Highly Likely / High Impact
● Medium	Less Likely / High Impact or Highly Likely/ Lower Impact
● Minor / Informative	Unlikely / Low to no Impact

Overview

The `lock_tokens_program` is a Solana smart contract built using the Anchor framework, designed to facilitate a token locking and distribution system. It allows users to deposit tokens into a vault during a specified window, which can later be swapped for payout tokens at a `1:1` ratio after a claim phase is opened by the contract owner. The program enforces strict access controls, time-based deposit and claim windows, and includes safety features like minimum deposit amounts, decimal validation, and emergency pause functionality. The contract supports secure token transfers, burns unclaimed tokens post-claim window, and emits events for transparency. It is designed for secure and controlled token swaps with robust error handling and state management.

Admin Functionality

The contract provides several owner-only functions to manage the token locking process. The `initialize` instruction sets up the `LockerConfig` with the deposit mint, deposit window, and claim window duration, restricted to an authorized initializer. The `set_payout_mint` instruction, callable only after the deposit window ends, assigns the payout mint and vault, ensuring decimal compatibility with the deposit mint to prevent mismatches. The `fund_payout_vault` instruction allows the owner to fund the payout vault with tokens matching the total deposited amount, while `open_claims` enables the claim phase post-deposit window. The `burn_unclaimed` function allows the owner to burn any unclaimed tokens after the claim window expires. Additionally, the `set_pause` function provides emergency control to halt or resume contract operations, ensuring governance flexibility. All admin actions are protected by ownership checks and time-based constraints.

Deposit

Users can deposit tokens into the contract's vault during the active deposit window using the `deposit` instruction. Deposits must meet a minimum amount (10_000 tokens) to prevent dust attacks and cannot exceed the maximum total deposit limit (50 billion tokens). The contract tracks each user's deposits in a `UserDeposit` account, updates the total deposited amount in `LockerConfig`, and transfers tokens to the deposit vault using the

SPL Token program. Deposits are blocked if the claim phase is active or the contract is paused, ensuring controlled deposit periods.

Fund Payout Vault

The `fund_payout_vault` instruction enables the contract owner to fund the payout vault with payout tokens matching the total deposited amount, ensuring a `1:1` swap ratio. This can only occur after the deposit window ends and the payout mint is set, with checks to prevent re-funding and ensure the correct mint is used. The tokens are transferred from the owner's associated token account to the payout vault, marking the vault as funded and enabling claims.

Open Claims

The `open_claims` instruction, restricted to the owner, activates the claim phase after the deposit window closes and the payout vault is funded. It sets the claim window duration based on the configured minutes, allowing users to claim their payout tokens within this period. The instruction ensures the contract is not paused and the payout mint is set, maintaining secure state transitions.

Claim

Users can claim their payout tokens during the claim window using the `claim` instruction. The contract verifies the user is the original depositor, the claim phase is active, the payout vault is funded, and the claim window has not expired. It transfers the user's deposited amount (in payout tokens) from the payout vault to the user's associated token account, updates the total claimed amount, and closes the `UserDeposit` account to reclaim rent. The instruction uses PDA signer seeds for secure token transfers and includes checks to prevent over-claiming or reentrancy attacks.

Burn Unclaimed

After the claim window expires, the owner can call `burn_unclaimed` to burn any remaining tokens in the payout vault. This instruction ensures the claim window is closed, the contract is not paused, and the payout mint is set. It uses the SPL Token program's

`burn` function with PDA signer seeds to destroy unclaimed tokens, ensuring no tokens remain locked in the vault indefinitely.

Pause and Unpause

The `set_pause` instruction allows the owner to halt or resume contract operations in emergencies. Pausing prevents deposits, claims, funding, mint setting, or burning, while unpausing restores normal functionality. The action is restricted to the owner and includes checks to avoid redundant state changes, ensuring secure and controlled contract management.

Reward Distribution Mechanism

The lock_tokens_program does not implement a traditional reward distribution system but instead facilitates a `1:1` token swap mechanism. Users deposit tokens into a vault, and after the deposit window closes, the owner funds the payout vault with an equivalent amount of payout tokens. During the claim phase, users receive payout tokens proportional to their deposited amount, with no additional rewards or weighting applied. The system ensures fairness by enforcing a direct `1:1` correspondence between deposited and claimed tokens, validated through strict accounting and vault balance checks.

Summary

The `lock_tokens_program` provides a secure, owner-managed system for locking tokens and distributing payout tokens on a `1:1` basis, with robust safeguards like time-based windows, minimum deposit thresholds, and emergency pause functionality. This audit examines the contract's security, business logic, and potential optimizations to ensure it is production-ready, focusing on correctness, efficiency, and resilience against common vulnerabilities.

CCR - Contract Centralization Risk

Criticality	Minor / Informative
Location	lib.rs#L98,187,229,254,353
Status	Unresolved

Description

The contract's functionality and behavior are heavily dependent on external parameters or configurations. While external configuration can offer flexibility, it also poses several centralization risks that warrant attention. Centralization risks arising from the dependence on external configuration include Single Point of Control, Vulnerability to Attacks, Operational Delays, Trust Dependencies, and Decentralization Erosion.

```rust
pub fn set_payout_mint(ctx: Context<SetPayoutMint>) -> Result<()>
{...}
 pub fn fund_payout_vault(ctx: Context<FundPayoutVault>) ->
Result<()> {...}
 pub fn open_claims(ctx: Context<OpenClaims>) -> Result<()> {...}
 pub fn set_pause(ctx: Context<EmergencyPause>, pause: bool) ->
Result<()> {...}
pub fn burn_unclaimed(ctx: Context<BurnUnclaimed>) -> Result<()>
{...}
```

Recommendation

To address this finding and mitigate centralization risks, it is recommended to evaluate the feasibility of migrating critical configurations and functionality into the contract's codebase itself. This approach would reduce external dependencies and enhance the contract's self-sufficiency. It is essential to carefully weigh the trade-offs between external configuration flexibility and the risks associated with centralization.

DBPI - Deposit Before Payout Initialization

Criticality	Minor / Informative
Location	lib.rs#L98
Status	Unresolved

Description

The contract operates under the assumption that users deposit tokens prior to the configuration for a payout. If a payout mint token is not set, the assets of users may remain locked in the contract.

```
pub fn set_payout_mint(ctx: Context<SetPayoutMint>) -> Result<()>
{...}
```

Recommendation

The team is advised to revise the protocol to ensure necessary configurations are provided before user deposits. This would enhance consistency and user trust. Alternatively, the team should consider implementing a refund mechanism in accordance with the recommendation of the finding `IDT`.

FER - Fixed Exchange Ratio

Criticality	Minor / Informative
Location	lib.rs#L329
Status	Unresolved

Description

The contract facilitates a 1:1 token exchange ratio. This design lacks flexibility and discourages the use of assets with differing financial values. Additionally, it could lead to misconfigurations and potential loss of funds if tokens with varying values are provided.

```
token::transfer(
CpiContext::new_with_signer(
ctx.accounts.token_program.to_account_info(),
    Transfer {
        from: ctx.accounts.payout_vault.to_account_info(),
        to: ctx.accounts.user_payout_ata.to_account_info(),
        authority: ctx.accounts.config.to_account_info(),
        },
    signer,
    ),
claim_amount,
)?;
```

Recommendation

The team should consider scenarios where the underlying tokens have different monetary values. In such cases, it is advisable to monitor the exchange ratio using a decentralized oracle to ensure consistent fund valuation.

IDT - Inaccessible Deposited Tokens

Criticality	Minor / Informative
Location	lib.rs#L124,163
Status	Unresolved

Description

Tokens deposited into the contract cannot be accessed or withdrawn. Users can deposit tokens using the `deposit` method, receiving payout tokens once the `claim` method is enabled. However, the inability to withdraw deposited tokens may not align with the intended business logic.

```
token::transfer(
    CpiContext::new(
        ctx.accounts.token_program.to_account_info(),
        Transfer {
            from: ctx.accounts.user_deposit_ata.to_account_info(),
            to: ctx.accounts.deposit_vault.to_account_info(),
            authority: ctx.accounts.user.to_account_info(),
        },
    ),
    amount,
)?;
```

Recommendation

The team should review the implementation to ensure it aligns with the intended business design. If the underlying tokens hold monetary value, it may be of interest to retain access to these assets.

RP - Redundant Property

Criticality	Minor / Informative
Location	lib.rs#L85
Status	Unresolved

Description

In the `initialize` function the `ctx.accounts.config.deposit_mint_decimals`
property is set equal to `ctx.accounts.deposit_mint.decimals`. However this property
is never used in the rest of the contract's functionality, therefore it is redundant.

```
let decimals = ctx.accounts.deposit_mint.decimals;
...
cfg.deposit_mint_decimals = decimals;
```

Recommendation

It is recommended to remove redundant properties to enhance code readability and
optimization.

TSI - Tokens Sufficiency Insurance

Criticality	Minor / Informative
Location	lib.rs#L187
Status	Unresolved

Description

The tokens are not held within the contract itself. Instead, the contract is designed to provide the tokens from an external administrator. While external administration can provide flexibility, it introduces a dependency on the administrator's actions, which can lead to various issues and centralization risks.

```
pub fn fund_payout_vault(ctx: Context<FundPayoutVault>) ->
Result<()> {
    ...
    token::transfer(
        CpiContext::new(
            ctx.accounts.token_program.to_account_info(),
            Transfer {
                from:
ctx.accounts.owner_payout_ata.to_account_info(),
                to: ctx.accounts.payout_vault.to_account_info(),
                authority: ctx.accounts.owner.to_account_info(),
            },
        ),
        amount_to_fund,
    )?;
    ...
}
```

Recommendation

It is recommended to consider implementing a more decentralized and automated approach for handling the contract tokens. One possible solution is to hold the tokens within the contract itself. If the contract guarantees the process it can enhance its reliability, security, and participant trust, ultimately leading to a more successful and efficient process.

Summary

The PIKAMOON contract implements a bridge and locker mechanism. This audit examines security issues, business logic concerns, and potential improvements. PIKAMOON is an engaging project with a friendly and growing community. The smart contract analysis revealed no compiler errors or critical concerns.

This report is not nor should be regarded as an indication of the economics or value of any "product" or "asset" created by any team or project that contracts Cyberscope to perform a security assessment. This document does not provide any warranty or guarantee regarding the absolute bug-free nature of the technology analyzed, nor do they provide any indication of the technologies proprietors' business, business model or legal compliance. This report should not be used in any way to make decisions around investment or involvement with any particular project. This report represents an extensive assessment process intending to help our customers increase the quality of their code while reducing the high level of risk presented by cryptographic tokens and blockchain technology.

Blockchain technology and cryptographic assets present a high level of ongoing risk Cyberscope's position is that each company and individual are responsible for their own due diligence and continuous security Cyberscope's goal is to help reduce the attack vectors and the high level of variance associated with utilizing new and consistently changing technologies and in no way claims any guarantee of security or functionality of the technology we agree to analyze. The assessment services provided by Cyberscope are subject to dependencies and are under continuing development. You agree that your access and/or use including but not limited to any services reports and materials will be at your sole risk on an as-is where-is and as-available basis Cryptographic tokens are emergent technologies and carry with them high levels of technical risk and uncertainty. The assessment reports could include false positives false negatives and other unpredictable results. The services may access and depend upon multiple layers of third parties.

About Cyberscope

Cyberscope is a TAC blockchain cybersecurity company that was founded with the vision to make web3.0 a safer place for investors and developers. Since its launch, it has worked with thousands of projects and is estimated to have secured tens of millions of investors' funds.

Cyberscope is one of the leading smart contract audit firms in the crypto space and has built a high-profile network of clients and partners.
